Simulation Testbench

- Ran SSO simulations and compared IBIS and Spice results
- DUT has a LPDDR2 interface and can reach a data rate of 800Mbps
- Used post-layout netlists for spice buffers
- IBIS model includes the power modeling features (BIRD95 and BIRD98)
- Package model is related to a MCP that contains the DUT
- PCB load: transmission line $Z_0=50$; $T_d=300\text{ps}$; $C_L=3.5\text{pF}$
- Output driver strength: 60 Ohm

Summary of Analysis

Four different cases of PDN model were used for IBIS simulations and the obtained results were compared to SPICE ones:

Case 1: no PDN model

Case 2: a capacitance only (100pF) added on the power nodes of each buffer

Case 3: an equivalent impedance (R-C) extracted manually by fitting the AC waveforms

Case 4: an equivalent spice model extracted by an automatic tool based on vector fitting

Case 1: No PDN Model

IBIS testbench generates a higher power drop than SPICE one

Case 2: Capacitance added to power nodes

Unexpected worse and strange (maybe unreal) power noise behaviour

Case 3: Equivalent impedance (R-C) extracted manually

Better agreement between IBIS and SPICE results and the strange (maybe unreal) power noise has disappeared

Case 4: Equivalent impedance by vector fitting

Further improvement of IBIS vs SPICE agreement

PDN Modeling

- ▶ The RC model was extracted by running an AC analysis between power nodes of SPICE netlist and then fitting manually the magnitude and phase waveforms.
- ▶ The macromodel extracted by a vector fitting tool is a spice subcircuit that mimics the frequency behavior of PDN. Its input was the S11 parameter.

Power Network AC Analysis

In case of "**C only**" model, a resonance was introduced at mid-frequency, but it was unreal and not confirmed by more accurate models like R-C and VF.

PDN models effectiveness comparison: Power Noise

PDN models effectiveness comparison: Data signal

Conclusions

- Sometimes a PDN model based on an equivalent capacitance only may be harmful to PI/SI IBIS simulation accuracy, generating unreal resonances.
- For this DUT the power noise was not too large because the IC and package PDN were well designed, but two main lessons have come up from this analysis:
 - a) To allow an effective use of IBIS power integrity features (BIRD95/98), it is strongly recommended to reproduce as accurately as possible the actual power noise
 - b) A frequency-dependent PDN model is advised, possibly extracted by a Vector Fitting tool
- Although in this case the two frequency-dependent PDN models (R-C and VF) seem equivalent, that's not always true. Sometimes the manual fitting may be very complex and difficult to cover the whole frequency range of interest.
