

Quality of S-parameter models

Asian IBIS Summit, Yokohama, November 18, 2011

Yuriy Shlepnev shlepnev@simberian.com

Outline

- Introduction
- S-parameters in frequency and time domains
- Constrains on S-parameters in frequency domain
- Quality metrics for reciprocity, passivity, causality
- Rational approximation and final quality metric
- Conclusion
- Contacts and resources

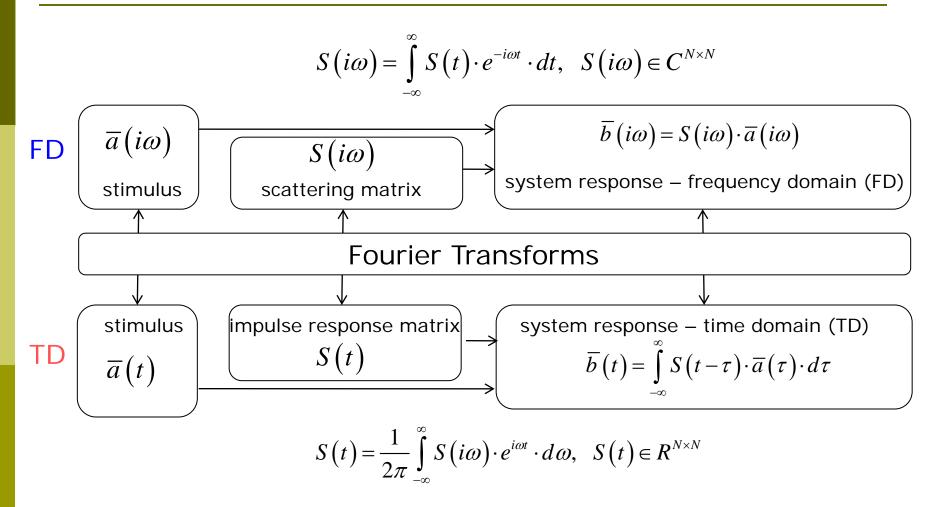

S-parameter models

- S-parameter models are becoming ubiquitous in design of multi-gigabit interconnects
 - Connectors, cables, PCBs, packages, backplanes, ..., any LTIsystem in general can be characterized with S-parameters from DC to daylight
- Electromagnetic analysis or measurements are used to build S-parameter Touchstone models
- Very often such models have quality issues:
 - Reciprocity violations
 - Passivity and causality violations
 - Common sense violations
- And produce different time-domain and even frequencydomain responses in different solvers!

System response computation requires frequencycontinuous S-parameters from DC to infinity

10/23/2011

Possible approximations for discrete models

- Discrete Fourier Transform (DFT) and convolution
 - Slow and may require interpolation and extrapolation of tabulated S-parameters (uncontrollable error)
- Approximate discrete S-parameters with rational functions (RMS error)
 - Accuracy is under control over the defined frequency band
 - Frequency-continuous causal functions defined from DC to infinity with analytical impulse response
 - Fast recursive convolution algorithm to compute TD response
 - Results consistent in time and frequency domains
- Not all Touchstone models are suitable for either approach

5

Common S-parameter model defects

Model bandwidth deficiency

- S-parameter models are band-limited due to limited capabilities of solvers and measurement equipment
- Model should include DC point or allow extrapolation, and high frequencies defined by the signal spectrum

Model discreteness

- Touchstone models are matrix elements at a set of frequencies
- Interpolation or approximation of tabulated matrix elements may be necessary both for time and frequency domain analyses

Model distortions due to

- Measurement or simulation artifacts
- Passivity violations and local "enforcements"
- Causality violations and "enforcements"
- Human mistakes of model developers and users
- How to estimate and rate quality of the models?

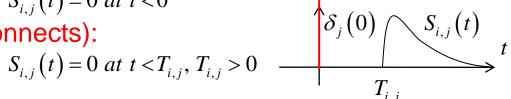

Causality of LTI system (TD & FD)

The system is causal if and only if all elements of the time-domain impulse response matrix are $S_{i,j}(t) = 0$ at t < 0

delayed causality (for interconnects):

$$S_{i,j}(t) = 0$$
 at $t < T_{i,j}, T_{i,j} > 0$

This lead to Kramers-Kronig relations in frequency-domain

$$S(i\omega) = \frac{1}{i\pi} PV \int_{-\infty}^{\infty} \frac{S(i\omega)}{\omega - \omega} \cdot d\omega, \ PV = \lim_{\varepsilon \to 0} \left(\int_{-\infty}^{\omega - \varepsilon} + \int_{\omega + \varepsilon}^{+\infty} \right)$$

$$S_{r}(\omega) = \frac{1}{\pi} PV \int_{-\infty}^{\infty} \frac{S_{i}(\omega)}{\omega - \omega} \cdot d\omega, \quad S_{i}(\omega) = \frac{-1}{\pi} PV \int_{-\infty}^{\infty} \frac{S_{r}(\omega)}{\omega - \omega} \cdot d\omega$$

Kramers, H.A., Nature, v 117, 1926 p. 775... Kronig, R. de L., J. Opt. Soc. Am. N12, 1926, p 547.

$$S(t) = sign(t) \cdot S(t),$$

$$sign(t) = \begin{vmatrix} -1, t < 0 \\ 1, t > 0 \end{vmatrix}$$

$$S(i\omega) = F\{S(t)\} =$$

$$= \frac{1}{2\pi} F\{sign(t)\} * F\{S(t)\}$$

$$F\left\{sign\left(t\right)\right\} = \frac{2}{i\omega}$$

derivation

Causality estimation - difficult way

- Kramers-Kronig relations cannot be directly used to verify causality for the frequency-domain response known over the limited bandwidth at some points
- Causality boundaries can be introduced to estimate causality of the tabulated and band-limited data sets
 - Milton, G.W., Eyre, D.J. and Mantese, J.V, Finite Frequency Range Kramers Kronig Relations: Bounds on the Dispersion, Phys. Rev. Lett. 79, 1997, p. 3062-3064
 - Triverio, P. Grivet-Talocia S., Robust Causality Characterization via Generalized Dispersion Relations, IEEE Trans. on Adv. Packaging, N 3, 2008, p. 579-593.

Even if test passes – a lot of uncertainties due to band limitedness

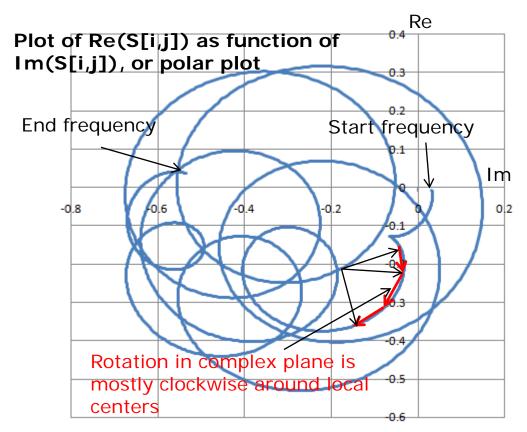

10/23/2011 © 2011 Simberian Inc.

8

Causality estimation - easy way

"Heuristic" causality measure based on the observation that polar plot of a causal system rotates mostly clockwise (suggested by V. Dmitriev-Zdorov)

Causality measure (CM) can be computed as the ratio of clockwise rotation measure to total rotation measure in %.

If this value is below 80%, the parameters are reported as suspect for possible violation of causality.

Algorithm is good for numerical models (to find under-sampling), but no so good for measured data due to noise!

9

Simberian Electromagnetic Solutions

Stability and passivity in time-domain

The system is stable if output is bounded for all bounded inputs

$$|a(t)| < K \Rightarrow |b(t)| < M, \forall t$$
 (BIBO)

A multiport network is passive if energy absorbed by multiport

$$E(t) = \int_{0}^{t} \left[\overline{a}^{t}(\tau) \cdot \overline{a}(\tau) - \overline{b}^{t}(\tau) \cdot \overline{b}(\tau) \right] \cdot d\tau \ge 0, \ \forall t$$
 (does not generate energy)

for all possible incident and reflected waves

$$\overline{a}(t) = 0, \ \forall t < t_0 \Rightarrow \int_{-\infty}^{t} \left[\overline{b}^{t}(\tau) \cdot \overline{b}(\tau) \right] \cdot d\tau \le 0 \Rightarrow \overline{b}(t) = 0, \ \forall t < t_0$$

Thus, we need to check only the passivity of interconnect system!

P. Triverio S. Grivet-Talocia, M.S. Nakhla, F.G. Canavero, R. Achar, Stability, Causality, and Passivity in Electrical Interconnect Models, IEEE Trans. on Advanced Packaging, vol. 30. 2007, N4, p. 795-808.

10/23/2011

Passivity in frequency domain

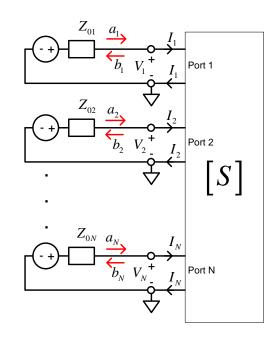

Power transmitted to multiport is a difference of power transmitted by incident and reflected waves: $P_{in} = \sum_{n=1}^{N} |a_n|^2 - |b_n|^2 = \left[\overline{a}^* \cdot \overline{a} - \overline{b}^* \cdot \overline{b}\right]$

or
$$P_{in} = \overline{a}^* \cdot \overline{a} - \overline{a}^* \cdot S^* S \cdot \overline{a} = \overline{a}^* \cdot \left[U - S^* S \right] \cdot \overline{a}$$

Quadratic form is non-negative if eigenvalues of the matrix are non-negative:

$$eigenvals [U - S^* \cdot S] \ge 0 \implies eigenvals [S^* \cdot S] \le 1$$
(*U* is unit matrix)

Sufficient condition only if verified from DC to infinity (impossible for discrete Touchstone models)

10/23/2011

© 2011 Simberian Inc.

Good Touchstone models of interconnects

- Must have sufficient bandwidth matching signal spectrum
- Must be appropriately sampled to resolve all resonances
- Must be reciprocal (linear reciprocal materials used in PCBs)

$$S_{i,j} = S_{j,i}$$
 or $S = S^t$

Must be passive (do not generate energy)

$$P_{in} = \overline{a}^* \cdot \left[U - S^* S \right] \cdot \overline{a} \ge 0$$
 \Longrightarrow eigenvals $\left[S^* \cdot S \right] \le 1$ from DC to infinity!

■ Have causal step or impulse response (response only after the excitation) $S_{i,j}(t)$

Sition)
$$S_{i,j}(t) = 0, t < T_{ij}$$

$$T_{i,j}$$

Quality metrics (0-100%) to define goodness

First introduced at IBIS forum at DesignCon 2010

Passivity Quality Measure:

$$PQM = \max \left[\frac{100}{N_{total}} \left(N_{total} - \sum_{n=1}^{N_{total}} PW_n \right), 0 \right] \% \qquad PW_n = 0 \ if \ PM_n < 1.00001; \ otherwise PW_n = \frac{PM_n - 1.00001}{0.1}$$

$$Should be > 99\% \qquad PM_n = \sqrt{\max \left[eigenvals \left(S^* \left(f_n \right) \cdot S \left(f_n \right) \right) \right]}$$

Reciprocity Quality Measure:

$$RQM = \max \left[\frac{100}{N_{total}} \left(N_{total} - \sum_{n=1}^{N_{total}} RW_n \right), 0 \right] \% \qquad RW_n = 0 \ if \ RM_n < 10^{-6}; \ otherwise \ RW_n = \frac{RM_n - 10^{-6}}{0.1}$$
 should be $> 99\%$
$$RM_n = \frac{1}{N_s} \sum_{i,j} \left| S_{i,j} \left(f_n \right) - S_{j,i} \left(f_n \right) \right|$$

 Causality Quality Measure: Minimal ratio of clockwise rotation measure to total rotation measure in % (should be >80% for numerical models)

Preliminary quality estimation metrics

 Preliminary Touchstone model quality can be estimated with Passivity, Reciprocity and Causality quality metrics (PQM, RQM, CQM)

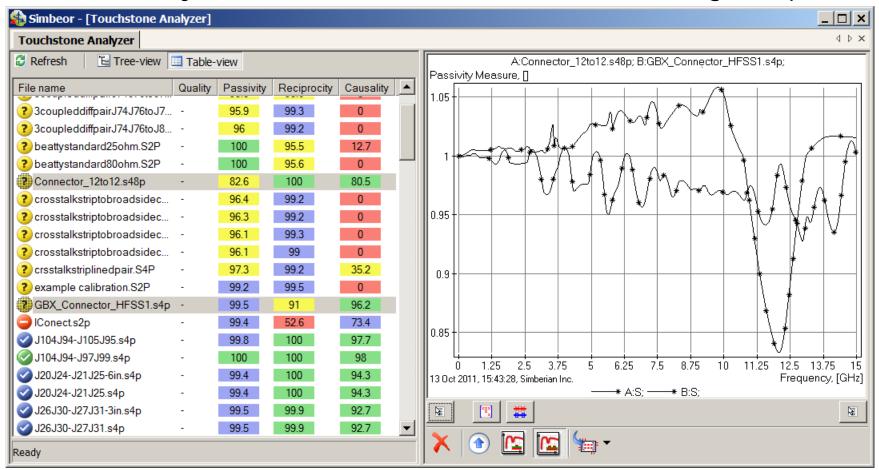

Metric/Model Icon	🥝 - good	acceptable	inconclusive	🔵 - bad
Passivity	[100, 99.9]	(99.9, 99]	(99, 80]	[80, 0]
Reciprocity	[100, 99.9]	(99.9, 99]	(99, 80]	[80, 0]
Causality	[100, 80]	(80, 50]	(50, 0]	

Color code	Passivity (PQM)	Reciprocity (RQM)	Causality (CQM)
Green – good	[99.9, 100]	[99.9, 100]	[80, 100]
Blue – acceptable	[99, 99.9)	[99, 99.9)	[50, 80)
Yellow – inconclusive	[80, 99)	[80, 99)	[20, 50)
Red - bad	[0, 80)	[0, 80)	[0, 20)

Example of preliminary quality estimation

Small passivity & reciprocity violations in most of the models Low causality in some measured data due to noise at high frequencies

© 2011 Simberian Inc.

Rational approximation of S-parameters as the frequency-continuous model

$$\overline{b} = S \cdot \overline{a}, \quad S_{i,j} = \frac{b_i}{a_j} \bigg|_{a_k = 0 \text{ } k \neq j} \Rightarrow S_{i,j} \left(i\omega \right) = \left[d_{ij} + \sum_{n=1}^{N_{ij}} \left(\frac{r_{ij,n}}{i\omega - p_{ij,n}} + \frac{r_{ij,n}^*}{i\omega - p_{ij,n}^*} \right) \right] \cdot e^{-s \cdot T_{ij}} \quad \text{Continuous functions of frequency defined}$$

from DC to infinity

 $s = i\omega$, d_{ii} -values at ∞ , N_{ii} -number of poles,

 $r_{ij,n}$ – residues, $p_{ij,n}$ – poles (real or complex), T_{ij} – optional delay

Pulse response is analytical, real and delay-causal:

$$S_{i,j}(t) = 0, \ t < T_{ij}$$

$$S_{i,j}(t) = d_{ij}\delta(t - T_{ij}) + \sum_{n=1}^{N_{ij}} \left[r_{ij,n} \cdot \exp(p_{ij,n} \cdot (t - T_{ij})) + r_{ij,n}^* \cdot \exp(p_{ij,n}^* \cdot (t - T_{ij})) \right], \ t \ge T_{ij}$$

- Stable $Re(p_{ij,n}) < 0$
- □ Stable $\ker(P_{ij,n}) \sim$ □ Passive if $eigenvals[S(\omega) \cdot S^*(\omega)] \leq 1 \ \forall \omega, \ from \ 0 \ to \infty$
- Reciprocal if $S_{i,i}(\omega) = S_{i,i}(\omega)$

Rational approximation can be used to

- Compute time-domain response of a channel with a fast recursive convolution algorithm (exact solution for PWL signals)
- Improve quality of tabulated Touchstone models
 - Fix minor passivity and causality violations
 - Interpolate and extrapolate with guarantied passivity
- Produce broad-band SPICE macro-models
 - Smaller model size, stable analysis
 - Consistent frequency and time domain analyses in any solver
- Measure the original model quality

Final quality estimation

Accuracy of discrete S-parameters approximation with frequency-continuous macro-model, passive from DC to infinity

$$RMSE = \max_{i,j} \left[\sqrt{\frac{1}{N} \sum_{n=1}^{N} \left| S_{ij}(n) - S_{ij}(\omega_n) \right|^2} \right]$$

Can be used to estimate quality of the original data

$$Q = 100 \cdot \max(1 - RMSE, 0)\%$$

Model Icon/Quality	Quality Metric	RMSE
🕝 - good	[99, 100]	[0, 0.01]
	[90, 99)	(0.01, 0.1]
? - inconclusive	[50, 90)	(0.1, 0.5]
🔵 - bad	[0, 50)	> 0.5
2 - uncertain	[0,100], not passive or not reciprocal	

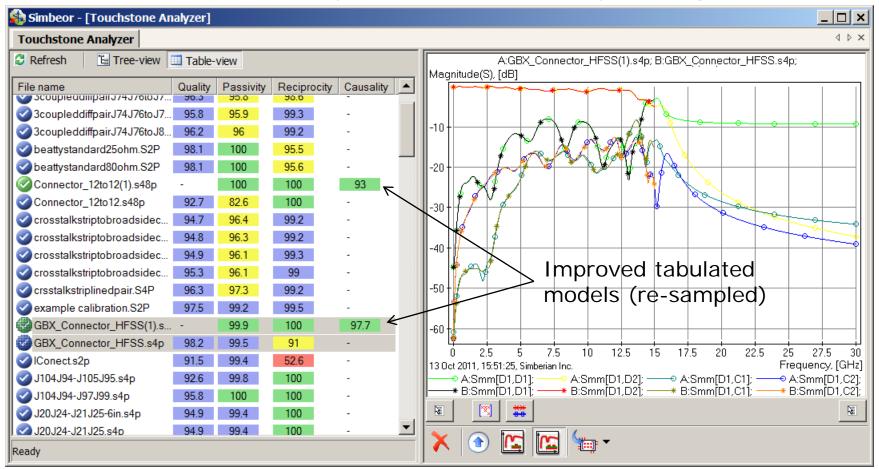

10/23/2011 © 2011 Simberian Inc.

18

Example of final quality estimation

All rational macro-models are passive, reciprocal, causal and have acceptable accuracy (acceptable quality of original models)

© 2011 Simberian Inc.

Conclusion: How to avoid problems with S-parameter models?

- Use reciprocity, passivity and causality metrics for preliminary analysis
 - RQM and PQM metrics should be > 99% (acceptable level)
 - CQM should be > 80% for all causal numerical models
- Use the rational model accuracy as the final quality measure
 - QM should be > 90% (acceptable level)
- Discard the model with low RQM, PQM and QM metrics!
 - The main reason is we do not know what it should be
- Models that pass the quality metrics may still be not usable or mishandled by a system simulator
 - Due to band-limitedness, discreteness and brut force model fixing
- Use rational or BB SPICE macro-models instead of Touchstone models for consistent time and frequency domain analyses
